DeFi charges everyone the same price for being a stranger

Aave and Compound require 150 to 200 percent collateral from every borrower, without exception. A wallet that has repaid 40 loans over two years is priced exactly like a wallet created five minutes ago.

Capital sits idle

Every extra dollar of collateral is capital that is not lent, not earning, and not doing anything except sitting as excess security.

Reputation has no value

A perfect repayment record cannot travel. It is locked inside Ethereum contract storage, and it cannot be proven anywhere else, including on the chain built around credit.

On-chain credit scoring is five years old and still has no economic traction

- **They sell a number you have to trust.** A score computed off-chain, delivered as an assertion, with no way for a lender to check the evidence underneath it.
- **The ones that reached a market reached the wrong one.** Undercollateralized lending to anonymous wallets with no recourse. That product has been tried, and the losses are on record.

Corollary changes the output, not just the model.

Every loan stays fully over-collateralized. What a proven borrower gets is a smaller number, not a waived one. That single decision is what separates this from the category behind it.

Corolary proves real Ethereum mainnet lending history on Creditcoin, and turns it into a price. Required collateral falls from 150 percent to 110 percent.

Not uncollateralized lending. Proven borrowers simply lock far less capital, and every number can be traced back to a real mainnet transaction.

Three layers on one proof

An indexer watches Aave V3, Morpho Blue, SparkLend and Compound V3 on Ethereum mainnet, waits for attester consensus, buys proofs in batches, and submits them to Creditcoin.

Attestcoin is not a feature here. It is the floor

Mainnet only	FactRegistry accepts chainKey 3, Ethereum mainnet, and nothing else. Sepolia returns false by contract policy, so nobody can farm a score with tokens they minted themselves.
Inclusion is not success	The Block Prover proves a transaction was included in a mined block, not that it succeeded. Every path decodes the receipt and requires receiptStatus 1 before recording anything.
Emitter validation	Proving a log exists is not proving it came from Aave. The decoder is selected by the emitting address, so a copycat contract emitting fake events has no valid path in.
Eager proving	A proof built inside the cheap window costs roughly 10x less. We prove events while they are fresh and store the fact permanently, never on demand in a hot path.
Batched verification	One call amortizes cost across up to 10 transactions within a 999 block span. The batch is all or nothing, so a corrupt member is split out rather than retried.

One fact, opened all the way down

A score in this product is never an assertion. Open any component, pick any fact, and the chain of custody is on screen.

What is real here, and the one thing that is testnet

Credit history	Real Ethereum mainnet transactions, proven cryptographically
Prices	Real Chainlink mainnet feeds, proven cryptographically
Scores	Computed on-chain from those proven facts
Market tokens	tUSDC and tWETH are testnet ERC-20s

The market tokens are testnet tokens. The credit history, the prices, and the scores come from real Ethereum mainnet.

The hackathon requires a testnet deployment and CC3 has no real USDC. Testnet tokens are the container, never the data. tUSDC is itself priced using genuine mainnet USDC proven through Chainlink.

Faking a history costs the same as having one

Mainnet gas is the toll

Every fact behind a score is a real Ethereum transaction that someone already paid for. There is no cheap chain to manufacture a record on, because chainKey 3 is the only one accepted.

Time cannot be bought

History duration is measured from the first proven fact. A wallet created today cannot buy its way to a two year record at any price.

Self dealing earns nothing

Compound base asset flows are deliberately not mapped, because supplying and repaying are indistinguishable there. Only unambiguous events count.

Every check lives in the contract rather than in an off-chain policy, so the rules are readable by the same people who are subject to them.

Five streams on one set of facts

Origination fee	0.5 percent of principal, taken once at drawdown. A 10,000 dollar loan pays 50 dollars.
Interest spread	1 to 2 percent between what borrowers pay and what suppliers receive. Recurring while the position is open.
Credit Graph API	Protocols that want to read Corolary scores for their own underwriting pay for access beyond the free tier. Recurring, not a one time purchase.
Sponsored facts	A lending protocol that wants its events indexed and proven can fund the integration and the ongoing proving cost, and reach an already verified borrower base.
B2B licensing	Credal serves off-chain credit data to fintech lenders. Corolary supplies the crypto-native half it has never had.

Costs are measured in fractions of a cent, revenue in dollars

2.59e-5

CTC PER FACT, EAGER

10x

CHEAPER THAN LAZY
PROVING

\$50

FEE ON A \$10,000 LOAN

~100%

GROSS MARGIN ON THAT
FEE

Reconstructing a borrower's full history costs a fraction of a cent in proving. Every additional reader of that same fact, whether an API subscriber or a licensed partner, is revenue with no marginal proving cost at all. This is a data infrastructure cost curve, not a lending one.

The wedge is narrow on purpose

TIER	COLLATERAL PER \$100	CAPITAL FREED
Unproven, 150 percent	\$150	baseline
Mid tier, 130 percent	\$130	\$20
Proven, 110 percent	\$110	\$40

Illustration of the mechanism, not a dollar projection. DeFi lending TVL moves with the cycle and is not quoted here as a precise figure.

Established DeFi users

Wallets with long Aave, Morpho and Compound histories looking to carry that record somewhere it pays. Measured in active wallets, not in TVL.

Creditcoin lender network

Credal and Aella already serve 337,000 customers and 79.7 million dollars of verified credit volume. Corolary adds a crypto-native score to a user base that already exists.

Corolary is not a competitor to Credal. It is the missing half

What Credal already knows

Who is creditworthy from off-chain financial history. Fintech loans, instalment payments, KYC. 4.27 million credit transactions, 79.7 million dollars in volume, 337,000 customers.

What Corolary adds

Who is creditworthy from on-chain financial history. DeFi borrowing and repayment, proven cryptographically, with no trusted third party data in the path.

Creditcoin was built by Gluwa around credit for emerging markets, and all of that traction is off-chain. The score layer drawn from crypto-native activity is the one piece the ecosystem does not have yet.

Four neighbouring categories. Nobody combines them, and nobody is on Creditcoin

CATEGORY	WHAT THEY BUILT	WHERE COROLARY DIFFERS
On-chain credit scores	Spectral, Cred, ARCx, Credora. Active, and the category is five years old.	Their score is an assertion. Ours is on-chain and every component names its evidence.
Undercollateralized lending	Loans to anonymous wallets with no recourse.	We refuse this space. Every loan here stays over-collateralized.
Proof infrastructure	Axiom, Herodotus, Brevis. Query per request against historical state.	We pay once and store the fact forever. Reads are free after that, for everyone.
Cross-chain oracles	A committee attests to data and you trust the committee.	Verification is synchronous, in the contract, against the source chain itself.

What funding buys, in order

MONTHS 1 TO 3

Bootstrap

Open the Credit Graph API with a free tier for builders. Begin onboarding established DeFi users. Widen protocol coverage on the adapters already specified.

WITH CEIP FUNDING

Security and coverage

Professional contract audit before real TVL. More Ethereum protocols, and more source chains the moment Attestcoin supports them, with no change to the core architecture.

CONDITIONAL

Writability

Attestcoin writability is still in audit. Once it ships, a proven score can be written back to Ethereum and used in the protocols it came from. A roadmap item, not a timeline promise.

Two builders, one rule

Wangsit Nursyahada

Contracts, indexer and API. The four Solidity contracts, the Attestcoin proof pipeline across four mainnet protocols, and the service layer behind the product.

Nabil Aufa Danaputra

Frontend. The score explorer, the proof viewer that opens a single fact down to its Ethereum transaction, and the lending market interface.

No number in this product comes from anywhere except a real Ethereum mainnet transaction or real Creditcoin contract state. A CI gate enforces it.
